

NPM-ALK

John K. Everett

2019-05-16

This analysis examines the effect of NPM-ALK transgenes delivered to CD4 T-cells by means of a lentiviral vector. Four NPM-ALK transgenes were studied: a naturally occurring NPM-ALK fusion (WT), a NPM-ALK triple mutant (TrpM), NPM-ALK with no kinase activity (KD), and a singly substituted transgene (Y664F). Wild type NPM-ALK is known to transform T-cells where Y664F has been shown to transform cells more efficiently. WT and Y664 transformation is dependent upon an active kinase domain. The triple mutant (Y567F, Y644F, Y646F) is of particular interest because it begins to transform T-cells at early time points similar to WT though these cells lose their CD30 marking and begin to die after three weeks similar to KD clones (Figure 1).

Figure 1. Cell sorting experiments.

RNAseq analyses were performed in order to identify changes in the transcriptome of clones (WT, Y664F, and KD) at different time points. While KD clones possessed transcriptomes rather similar to uninfected cells, WT and Y664F clones possessed transcriptomes distinct from KD. In the PCA analysis (Figure 2), WT and Y664F clones moved downward in the plot over time where the Y664F clones move downward faster which may explain in part why they transform cells more effectively.

Figure 2. RNAseq of WT, Y664F, KD, and uninfected cells at different time points. Different donors are denoted with numbers.

Comparing WT clone transcription levels (days 9, 12, 33, and 63) to day 6 reveals a number of genes with transcription levels that significantly change over time (Figure 3).

Figure 3. RNAseq of WT clones compared to the earliest WT clone. Genes are ordered from the most significant transcription change (top) to less significant changes (bottom). Genes shown are the more significant genes which can easily be visualized in a single figure.

Comparing Y664F clone transcription levels to WT clones at the same time point reveals significant changes in the transcription of select genes (Figure 4). The most significant change in transcription atop of Figure 4, MYD88, may be of interest.

Figure 4. RNAseq of Y664F clone compared to WT clones at the same time points. Genes are ordered from the most significant transcription change (top) to less significant changes (bottom). Genes shown are the more significant genes which can easily be visualized in a single figure.

A second RNAseq analysis was performed in order to identify changes in the transcriptome of WT, TrpM, and KD at different time points. Time points of day 6 and day 9 were selected as time points of interest because they mark the beginning of cellular transformation and the beginning of CD30 loss in TrpM clones. Figure 5 shows a RNAseq PCA analysis which clearly separates clones and time points with the TrpM clones plotted between WT and KD samples which is reflective of TrpM’s inability to fully transform cells.

Figure 5. PCA analysis of RNAseq experiment of WT, TrpM and KD clones.

WT and TrpM genes with the most significantly different changes in transcription compared to KD clones is shown in Figure 6.

Figure 6. RNAseq analyses of WT and TrpM clones compared to KD clones. Genes are ordered from the most significant change (top left) to less significant changes (bottom right) where the second heatmap on the right is a continuation of the heatmap on the left.

Comparing TrpM clones to WT clones reveals a number of genes with significantly different transcription levels most of which are lower in the TrpM clones (Figure 7).

Figure 7. RNAseq analyses of TrpM clones compared to WT clones. Genes are ordered from the most significant change (top) to less significant changes (bottom). Genes shown are the more significant genes which can easily be visualized in a single figure.

Table 1. Enriched pathways from the day 9 WT vs KD RNAseq comparison. Genes with increased transcription are shown with uppercase names while genes with decreased transcription are shown with lowercase names. Full table is provided in Table S1.

Viral integration site analysis of cultures transfected with both WT and Y664F transgenes show that cultures become oligoclonal over time. The relative clonal abundances of provided samples, arranged by earliest time point, are shown in Figure 8 where the relative abundances of the most abundant 50 clones are shown as stacked colored bars while less abundant clones are relegated to single gray low abundance bars.

Figure 8. Clonal relative abundance plots.

Integration profiles of cultures from three donors transfected with both WT and Y664F transgene were tracked over multiple time points and the rate at which they become oligoclonal is depicted in Figure 9.

Figure 9. Clonality of transfected cultures over time.

Some 753 clones (1.56% of all clones) in the longitudinal data set reached a maxim abundance of ≥ 25 cells at one or more time points (Figure 10). Four types of clonal abundance trajectories were observed:

1. Clones which were only observed at the earliest time points (98.44% of all clones).
2. Clones which reached a maximal abundance ≥ 25 cells by day 28 and then declined (Figure 10, top pane).
3. Clones which slowly increased in abundance and exceeded 25 cells (Figure 10, bottom pane, bottom cluster).
4. Clones which rapidly increased in abundance beyond 25 cells (Figure 10, bottom pane, top cluster).

The genes nearest to integration sites in clones from each clonal trajectory type do not substantially overlap with the enriched KEGG pathways genes found the WT vs KD day 9 RNAseq contrast (Table 1) nor do they strongly cluster to a discrete number of KEGG pathways (Table S2). The nearest genes for clones from each trajectory type are provided in Table S3.

Table 2. Clonal abundance trajectories clone counts.

Class	Clones	WT / Y664F
Type 2	706	184 / 522
Type 3	32	2 / 30
Type 4	15	6 / 9

Instances of clones with abundances ≥ 25 cells with integrations found near the same gene across multiple trial subjects are reported in Table 3.

Figure 10. Clonal abundance trajectories. Top pane: clones which exceeded abundances of 25 cells and then declined in later time points. Bottom pane: Subset of clones that exceeded abundances of 25 cells and reached their highest abundance at their final time point. Data points not connected with lines originate from clones which were not analyzed or detected at earlier time points presumably due to their low abundance.

Table 3. Tally of trial subjects with three or more abundant clones near the same gene.

Considering only donors with longitudinal trials and both WT and Y664F transgenes (pNA92, pNA93, pNA85), plotting nearest gene integration frequencies between early and later time points (Figure 11) show that ARID1A is placed more starkly above the diagonal in the Y664F trials than WT trials suggesting that it confers more of a survival advantage to clones with the Y664F transgene. Table 4 below shows the number of unique clones with integrations within ARID1A and their maximum abundance while Figure 12 shows the integration positions within ARID1A's transcription unit. Fisher's exact tests do not find a significant difference between the proportions of clones with maximal abundances < 25 and ≥ 25 cells which suggests that integration within ARID1A and higher clonal abundances are not dependent on the transgene though there is a trend toward higher abundances with the Y664F transgene.

Table 4. Unique clones with integrations within ARID1A separated by transgene and maximum observed abundance.

	Abund < 25	Abund ≥ 25
WT	24	1
Y664F	56	7

Figure 12. Schematic of ARID1A where exons are shown as gray bars and clones are shown by data points denoting both their integration position and maximum abundance.

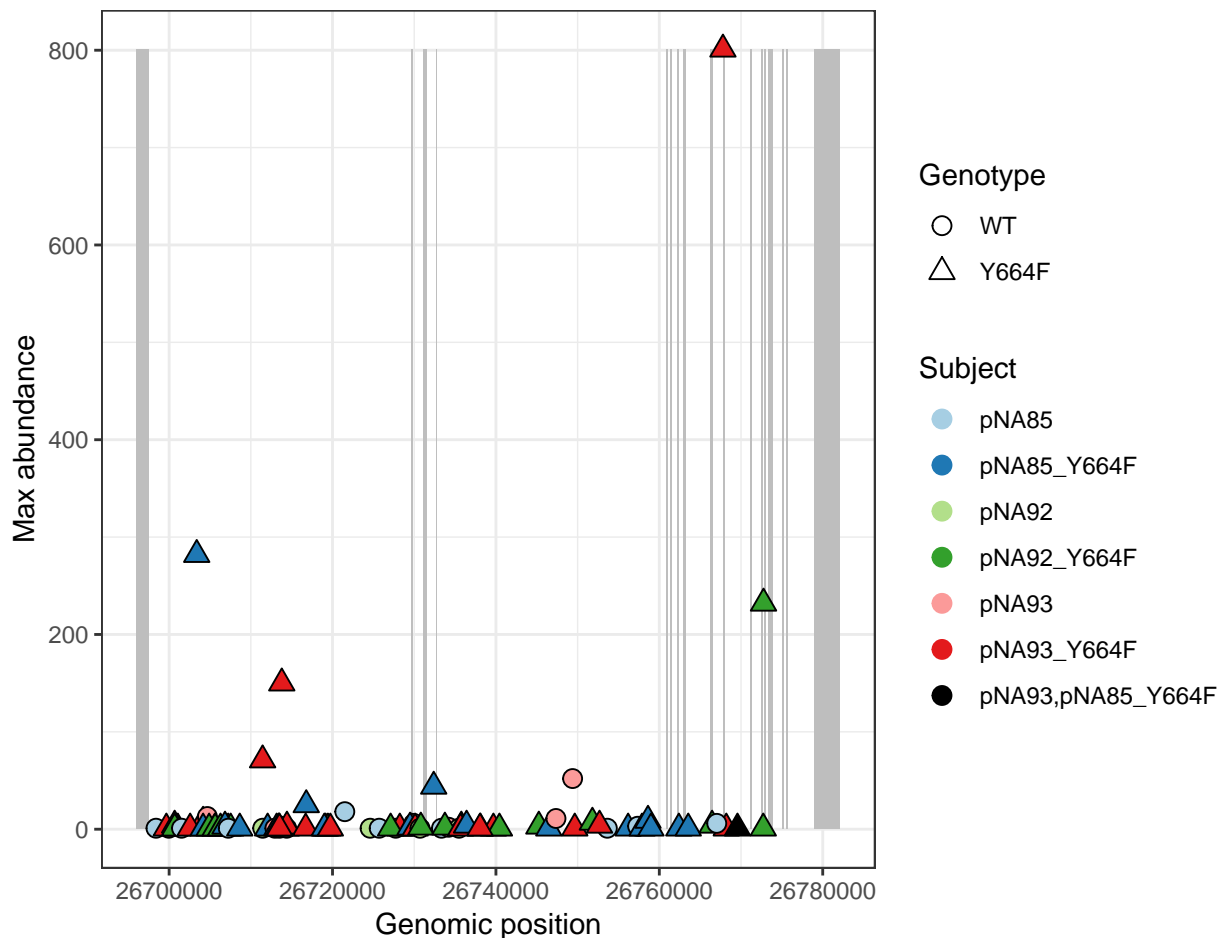

Figure 11a. Bivariate nearest gene frequency plot for clones with the Y664F transgene.

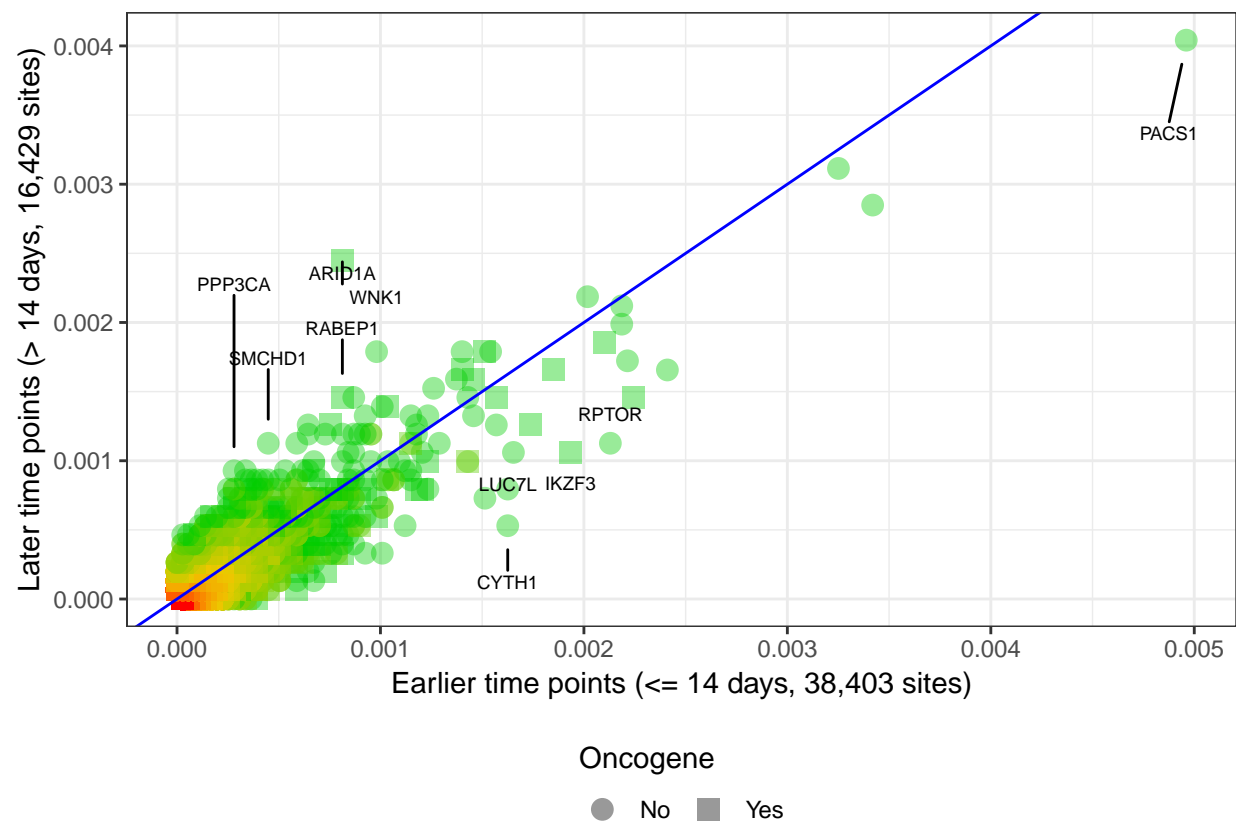

Figure 11b. Bivariate nearest gene frequency plot for clones with the WT transgene.
